Application Note AN-4151

Half-bridge LLC Resonant Converter Design Using FSFR-series Fairchild Power Switch (FPS™)

Introduction

The effort to obtain ever-increasing power density of switched-mode power supplies has been limited by the size of passive components. Operation at higher frequencies considerably reduces the size of passive components, such as transformers and filters; however, switching losses have been an obstacle to high-frequency operation. To reduce switching losses and allow high-frequency operation, resonant switching techniques have been developed. These techniques process power in a sinusoidal manner and the switching devices are softly commutated. Therefore, the switching losses and noise can be dramatically reduced [1-7].

Among various kinds of resonant converters, the simplest and most popular resonant converter is the LC series resonant converter, where the rectifier-load network is placed in series with the L-C resonant network, as depicted in Figure 1 [2-4]. In this configuration, the resonant network and the load act as a voltage divider. By changing the frequency of driving voltage $V_d$, the impedance of the resonant network changes. The input voltage is split between this impedance and the reflected load. Since it is a voltage divider, the DC gain of a LC series resonant converter is always <1. At light-load condition, the impedance of the load is very large compared to the impedance of the resonant network; all the input voltage is imposed on the load. This makes it difficult to regulate the output at light load. Theoretically, frequency should be infinite to regulate the output at no load.

To overcome the limitation of series resonant converters, LLC resonant converter has been proposed [8-12]. LLC resonant converter is a modified LC series resonant converter implemented by placing a shunt inductor across the transformer primary winding, as depicted in Figure 2. When this topology was first presented, it did not receive much attention due to the counterintuitive concept that increasing the circulating current in the primary side with a shunt inductor can be beneficial to circuit operation. However, it can be very effective in improving efficiency for high-input voltage application where the switching loss is much more dominant than the conduction loss.

In most of the practical design, this shunt inductor is realized using the magnetizing inductance of the transformer. The circuit diagram of LLC resonant converter looks much the same as the LC series resonant converter: the only difference is the value of the magnetizing inductor. While the series resonant converter has a magnetizing inductance much larger than the LC series resonant inductor ($L_r$), the magnetizing inductance in LLC resonant converter is just 3–8 times $L_r$, which is usually implemented by introducing an air gap in the transformer.

![Diagram of LLC Resonant Converter](image)

An LLC resonant converter has many advantages over a series resonant converter; it can regulate the output over wide line and load variations with a relatively small variation of switching frequency. It can achieve zero voltage switching (ZVS) over the entire operating range. All essential parasitic elements, including junction capacitances of all semiconductor devices and the leakage inductance and magnetizing inductance of the transformer, are utilized to achieve soft-switching.

This application note presents design considerations of an LLC resonant half-bridge converter employing FSFR-series FPS™. It includes explanation of LLC resonant converter operation principle, designing the transformer and resonant network, and selecting the components. The step-by-step design procedure explained with a design example helps design the LLC resonant converter.
1. LLC Resonant Converter and Fundamental Approximation

Figure 3 shows the simplified schematic of a half-bridge LLC resonant converter, where $L_m$ is the magnetizing inductance that acts as a shunt inductor, $L_r$ is the series resonant inductor, and $C_r$ is the resonant capacitor. Figure 4 illustrates the typical waveforms of the LLC resonant converter. It is assumed that the operation frequency is same as the resonance frequency, determined by the resonance between $L_r$ and $C_r$. Since the magnetizing inductor is relatively small, there exists considerable amount of magnetizing current ($I_m$), which freewheels in the primary side without being involved in the power transfer. The primary-side current ($I_p$) is sum of the magnetizing current and the secondary-side current referred to the primary.

In general, the LLC resonant topology consists of three stages shown in Figure 3: square wave generator, resonant network, and rectifier network.

- The square wave generator produces a square wave voltage, $V_d$, by driving switches Q1 and Q2 alternately with 50% duty cycle for each switch. A small dead time is usually introduced between the consequent transitions. The square wave generator stage can be built as a full-bridge or half-bridge type.

- The resonant network consists of a capacitor, leakage inductances, and the magnetizing inductance of the transformer. The resonant network filters the higher harmonic currents. Essentially, only sinusoidal current is allowed to flow through the resonant network even though a square wave voltage is applied to the resonant network. The current ($I_p$) lags the voltage applied to the resonant network (that is, the fundamental component of the square-wave voltage ($V_d$) applied to the half-bridge totem pole), which allows the MOSFETs to be turned on with zero voltage. As shown in Figure 4, the MOSFET turns on while the voltage across the MOSFET is zero by flowing current through the anti-parallel diode.

- The rectifier network produces DC voltage by rectifying the AC current with rectifier diodes and capacitor. The rectifier network can be implemented as a full-wave bridge or center-tapped configuration with capacitive output filter.

The filtering action of the resonant network allows use of the fundamental approximation to obtain the voltage gain of the resonant converter, which assumes that only the fundamental component of the square-wave voltage input to the resonant network contributes to the power transfer to the output. Because the rectifier circuit in the secondary side acts as an impedance transformer, the equivalent load resistance is different from actual load resistance. Figure 5 shows how this equivalent load resistance is derived. The primary-side circuit is replaced by a sinusoidal current source, $I_{ac}$, and a square wave of voltage, $V_{RI}$, appears at the input to the rectifier. Since the average of $|I_{ac}|$ is the output current, $I_o$, $I_{ac}$ is obtained as:

$$I_{ac} = \frac{\pi \cdot I_o}{2} \sin(\omega t)$$

(1)

and $V_{RI}$ is given as:

$$V_{RI} = +V_o \quad \text{if } \sin(\omega t) > 0$$

$$V_{RI} = -V_o \quad \text{if } \sin(\omega t) < 0$$

(2)

where $V_o$ is the output voltage.

The fundamental component of $V_{RI}$ is given as:

$$V_{RI}^f = \frac{4V_o}{\pi} \sin(\omega t)$$

(3)

Since harmonic components of $V_{RI}$ are not involved in the power transfer, AC equivalent load resistance can be calculated by dividing $V_{RI}^f$ by $I_{ac}$ as:

$$R_{ac} = \frac{V_{RI}^f}{I_{ac}} = \frac{8}{\pi^2} \frac{V_o}{I_o} = \frac{8}{\pi^2} R_o$$

(4)

Considering the transformer turns ratio ($n=N_p/N_s$), the equivalent load resistance shown in the primary side is obtained as:

$$R_p = \frac{8n^2}{\pi^2} R_o$$

(5)
By using the equivalent load resistance, the AC equivalent circuit is obtained, as illustrated in Figure 6, where \( V_{d} \) and \( V_{RO} \) are the fundamental components of the driving voltage, \( V_{d} \) and reflected output voltage, \( V_{RO} (nV_{RI}) \), respectively.

\[
\begin{align*}
\omega_o R_C &= \frac{n V_{o}}{V_{d}} = \frac{n V_{RO}}{V_{d}} \\
\omega_o &= \frac{2n \cdot V_{o}}{\omega_o} \\
\frac{2n \cdot V_{o}}{\omega_o} &= \frac{n V_{RO}}{V_{d}}
\end{align*}
\]

where:

\[
L_p = L_o + L_r, \quad R_w = \frac{8n^2 R_o}{\pi}, \quad m = \frac{L_o}{L_r}
\]

\[
Q = \sqrt{\frac{L_o}{C_r}}, \quad \omega_o = \sqrt{\frac{1}{L_o C_r}}, \quad \omega_p = \frac{1}{\sqrt{L_o C_r}}
\]

As can be seen in Equation 6, there are two resonant frequencies. One is determined by \( L_o \) and \( C_r \), while the other is determined by \( L_r \) and \( C_r \).

Equation 6 shows the gain is unity at resonant frequency (\( \omega_o \)), regardless of the load variation, which is given as:

\[
M = \frac{2n \cdot V_o}{V_{in}} = \frac{(m - 1) \cdot \omega_o^2}{\omega_o^2 - \omega_p^2} = 1 \quad \text{at} \quad \omega = \omega_o \quad (7)
\]

The gain of Equation 6 is plotted in Figure 7 for different Q values with \( m=3, f_o=100\text{kHz}, \) and \( f_p=57\text{kHz} \). As observed in Figure 7, the LLC resonant converter shows gain characteristics that are almost independent of the load when the switching frequency is around the resonant frequency, \( f_o \). This is a distinct advantage of LLC-type resonant converter over the conventional series resonant converter. Therefore, it is natural to operate the converter around the resonant frequency to minimize the switching frequency variation.

The operating range of the LLC resonant converter is limited by the peak gain (attainable maximum gain), which is indicated with ‘*’ in Figure 7. It should be noted that the peak voltage gain does not occur at \( f_o \) or \( f_p \). The peak gain frequency where the peak gain is obtained exists between \( f_o \) and \( f_p \), as shown in Figure 7. As Q decreases (as load decreases), the peak gain frequency moves to \( f_p \) and higher peak gain is obtained. Meanwhile, as Q increases (as load increases), the peak gain frequency moves to \( f_o \) and the peak gain drops; thus, the full load condition should be the worst case for the resonant network design.

![Figure 7. Typical Gain Curves of LLC Resonant Converter (m=3)](image-url)
2. Consideration for Integrated Transformer

For practical design, it is common to implement the magnetic components (series inductor and shunt inductor) using an integrated transformer; where the leakage inductance is used as a series inductor, while the magnetizing inductor is used as a shunt inductor. When building the magnetizing components in this way, the equivalent circuit in Figure 6 should be modified as shown in Figure 8 because the leakage inductance exists, not only in the primary side, but also in the secondary side. Not considering the leakage inductance in the transformer secondary side generally results in an incorrect design.

\[ V_o = \frac{2n \cdot V_o}{V_n} \]

\[ M = \frac{L_p}{L_p - L_r} = m = \frac{L_p}{L_p} \quad \text{at } \omega = \omega_o \]

The gain at the resonant frequency \( (o_o) \) is fixed regardless of the load variation, which is given as:

\[ M = \frac{L_p}{L_p - L_r} = \sqrt{\frac{m}{m-1}} \]

The gain at the resonant frequency \( (o_o) \) is unity when using individual core for series inductor, as shown in Equation 7. However, when implementing the magnetic components with integrated transformer, the gain at the resonant frequency \( (o_o) \) is larger than unity due to the virtual gain caused by the leakage inductance in the transformer secondary side.

The gain of Equation 9 is plotted in Figure 10 for different \( Q^e \) values with \( m=3, f_o=100kHz, \) and \( f_p=57kHz. \) As observed in Figure 9, the LLC resonant converter shows gain characteristics almost independent of the load when the switching frequency is around the resonant frequency, \( f_o. \)
3. Consideration of Operation Mode and Attainable Maximum Gain

Operation Mode
The LLC resonant converter can operate at frequency below or above the resonance frequency \( f_0 \), as illustrated in Figure 10. Figure 11 shows the waveforms of the currents in the transformer primary side and secondary side for each operation mode. Operation below the resonant frequency (case I) allows the soft commutation of the rectifier diodes in the secondary side, while the circulating current is relatively large. The circulating current increases more as the operation frequency moves downward from the resonant frequency. Meanwhile, operation above the resonant frequency (case II) allows the circulating current to be minimized, but the rectifier diodes are not softly commutated. Below resonance operation is preferred for high output voltage applications, such as Plasma Display Panel (PDP) TV where the reverse recovery loss in the rectifier diode is severe. Below resonance operation also has a narrow frequency range with respect to the load variation since the frequency is limited below the resonance frequency even at no load condition.

On the other hand, above resonance operation has less conduction loss than the below resonance operation. It can show better efficiency for low output voltage applications, such as Liquid Crystal Display (LCD) TV or laptop adaptor, where Schottky diodes are available for the secondary-side rectifiers and reverse recovery problems are insignificant. However, operation at above the resonant frequency may cause too much frequency increase at light-load condition. Above frequency operation requires frequency skipping to prevent too much increase of the switching frequency.

Required Maximum Gain and Peak Gain
Above the peak gain frequency, the input impedance of the resonant network is inductive and the input current of the resonant network \( I_p \) lags the voltage applied to the resonant network \( V_d \). This permits the MOSFETs to turn on with zero voltage (ZVS), as illustrated in Figure 12. Meanwhile, the input impedance of the resonant network becomes capacitive and \( I_p \) leads \( V_d \) below the peak gain frequency. When operating in capacitive region, the MOSFET body diode is reverse recovered during the switching transition, which results in severe noise. Another problem of entering into the capacitive region is that the output voltage becomes out of control since the slope of the gain is reversed. The minimum switching frequency should be well limited above the peak gain frequency.
The available input voltage range of the LLC resonant converter is determined by the peak voltage gain. Thus, the resonant network should be designed so that the gain curve has an enough peak gain to cover the input voltage range. However, ZVS condition is lost below the peak gain point, as depicted in Figure 12. Therefore, some margin is required when determining the maximum gain to guarantee stable ZVS operation during the load transient and start-up. Typically 10–20% of the maximum gain is used as a margin for practical design, as shown in Figure 13.

![Figure 13. Determining the Maximum Gain](image)

Even though the peak gain at a given condition can be obtained by using the gain in Equation 6, it is difficult to express the peak gain in explicit form. To simplify the analysis and design, the peak gains are obtained using simulation tools and depicted in Figure 14, which shows how the peak gain (attainable maximum gain) varies with \( Q \) for different \( m \) values. It appears that higher peak gain can be obtained by reducing \( m \) or \( Q \) values. With a given resonant frequency \( (f_o) \) and \( Q \) value, decreasing \( m \) means reducing the magnetizing inductance, which results in increased circulating current. Accordingly, there is a trade-off between the available gain range and conduction loss.
4. Features of FSFR-series

FSFR-series is an integrated Pulse Frequency Modulation (PFM) controller and MOSFETs specifically designed for Zero Voltage Switching (ZVS) half-bridge converters with minimal external components. The internal controller includes an under-voltage lockout, optimized high-side / low-side gate driver, temperature-compensated precise current controlled oscillator, and self-protection circuitry. Compared with discrete MOSFET and PWM controller solution, FSFR-series can reduce total cost, component count, size and weight, while simultaneously increasing efficiency, productivity, and system reliability.

Figure 15. Package Diagram

Figure 16. Functional Block Diagram of FSFR-series
5. Design Procedure

In this section, a design procedure is presented using the schematic in Figure 17 as a reference. An integrated transformer with center tap, secondary side is used and input is supplied from power factor correction (PFC) pre-regulator. A DC/DC converter with 192W/24V output has been selected as a design example. The design specifications are as follows:

- Nominal input voltage: 400VDC (output of PFC stage)
- Output: 24V/8A (192W)
- Hold-up time requirement: 20ms (50Hz line freq.)
- DC link capacitor of PFC output: 220µF

[STEP-1] Define the system specifications

As a first step, define the following specification.

**Estimated efficiency** ($E_\text{eff}$): The power conversion efficiency must be estimated to calculate the maximum input power with a given maximum output power. If no reference data is available, use $E_\text{eff} = 0.88$–$0.92$ for low-voltage output applications and $E_\text{eff} = 0.92$–$0.96$ for high-voltage output applications. With the estimated efficiency, the maximum input power is given as:

$$P_\text{in max} = \frac{P_\text{o max}}{E_\text{eff}}$$

**Input voltage range** ($V_{\text{in min}}$ and $V_{\text{in max}}$): The maximum input voltage would be the nominal PFC output voltage as:

$$V_{\text{in max}} = V_{\text{PFC}}$$

Even though the input voltage is regulated as constant by PFC pre-regulator, it drops during the hold-up time. The minimum input voltage considering the hold-up time requirement is given as:

$$V_{\text{in min}} = V_{\text{PFC}} - \frac{2P_\text{o max}T_{\text{HU}}}{C_{\text{DL}}}$$

where $V_{\text{PFC}}$ is the nominal PFC output voltage, $T_{\text{HU}}$ is a hold-up time, and $C_{\text{DL}}$ is the DC link bulk capacitor.

(Design Example) Assuming the efficiency is 92%,

$$P_\text{in max} = \frac{192}{0.92} = 209W$$

$$V_{\text{in max}} = V_{\text{PFC}} = 400V$$

$$V_{\text{in min}} = \sqrt{V_{\text{PFC}}^2 - \frac{2 \times 209 \times 20 \times 10^{-6}}{220 \times 10^{-6}}} = 349V$$

[STEP-2] Determine the Maximum and Minimum Voltage Gains of the Resonant Network

As discussed in the previous section, it is typical to operate the LLC resonant converter around the resonant frequency ($f_0$) to minimize switching frequency variation. Since the input of the LLC resonant converter is supplied from PFC output voltage, the converter should be designed to operate at $f_0$ for the nominal PFC output voltage.

As observed in Equation 10, the gain at $f_0$ is a function of $m$ ($m=L_p/L_s$). The gain at $f_0$ is determined by choosing that value of $m$. While a higher peak gain can be obtained with a small $m$ value, too small $m$ value results in poor coupling of the transformer and deteriorates the efficiency. It is typical to set $m$ to be 3–7, which results in a voltage gain of 1.1–1.2 at the resonant frequency ($f_0$).
With the chosen \( m \) value, the voltage gain for the nominal PFC output voltage is obtained as:

\[
M_{\text{min}} = \sqrt{\frac{m}{m-1}} \cdot \frac{\text{V}_{\text{in}}}{f_o} 
\]

(14)

which would be the minimum gain because the nominal PFC output voltage is the maximum input voltage (\( V_{\text{in}}^{\text{max}} \)).

The maximum voltage gain is given as:

\[
M_{\text{max}} = \frac{V_{\text{in}}^{\text{max}}}{V_{\text{in}}^{\text{min}}} \cdot M_{\text{min}} 
\]

(15)

**[Design Example]** The ratio \( (m) \) between \( L_p \) and \( L_r \) is chosen as 5. The minimum and maximum gains are obtained as:

\[
M_{\text{min}} = \frac{V_{\text{in}}^{\text{max}}}{V_{\text{in}}^{\text{max}}/2} = \sqrt{\frac{5}{5-1}} = 1.12 \\
M_{\text{max}} = \frac{V_{\text{in}}^{\text{max}}}{349} \cdot 1.12 = 1.28 
\]

**[STEP-3] Determine the Transformer Turns Ratio \((n=N_p/N_s)\)**

With the minimum gain \((M_{\text{min}})\) obtained in STEP-2, the transformer turns ratio is given as:

\[
n = \frac{N_p}{N_s} = \frac{V_{\text{in}}^{\text{max}}}{2(V_{o} + V_{F})} \cdot M_{\text{min}} 
\]

(16)

where \( V_{F} \) is the secondary-side rectifier diode voltage drop.

**[Design Example]** assuming \( V_{F} \) is 0.9V,

\[
n = \frac{N_p}{N_s} = \frac{V_{\text{in}}^{\text{max}}}{2(V_{o} + V_{F})} \cdot M_{\text{min}} = \frac{400}{2(24 + 0.9)} \cdot 1.12 = 9.00 
\]

**[STEP-4] Calculate Equivalent Load Resistance**

With the transformer turns ratio obtained from Equation 16, the equivalent load resistance is obtained as:

\[
R_{\text{eq}} = \frac{8n^2 V_{o}^2}{\pi^2 P_o} 
\]

(17)

**[Design Example]**

\[
R_{\text{eq}} = \frac{8 \cdot 5^2 \cdot 9.0^2}{\pi^2 \cdot 197} = 197\Omega 
\]

**[STEP-5] Design the Resonant Network**

With \( m \) value chosen in STEP-2, read proper \( Q \) value from the peak gain curves in Figure 14 that allows enough peak gain. Considering the load transient and stable zero-voltage-switching (ZVS) operation, 10~20% margin should be introduced on the maximum gain when determining the peak gain. Once the \( Q \) value is determined, the resonant parameters are obtained as:

\[
C_r = \frac{1}{2\pi Q \cdot f_o \cdot R_{\text{eq}}} 
\]

(18)

\[
L_r = \frac{1}{(2\pi f_o)^2 C_r} 
\]

(19)

\[
L_p = m \cdot L_r 
\]

(20)

**[Design Example]**

As calculated in STEP-2, the maximum voltage gain \((M_{\text{max}})\) for the minimum input voltage \((V_{\text{in}}^{\text{min}})\) is 1.28. With 15% margin, a peak gain of 1.47 is required. \( m \) has been chosen as 5 in STEP-2 and \( Q \) is obtained as 0.4 from the peak gain curves in Figure 19. By selecting the resonant frequency as 100kHz, the resonant components are determined as:

\[
C_r = \frac{1}{2\pi Q \cdot f_o \cdot R_{\text{eq}}} = \frac{1}{2\pi \cdot 0.4 \cdot 100 \cdot 10^3 \cdot 197} = 20.2nF \\
L_r = \frac{1}{(2\pi f_o)^2 C_r} = \frac{1}{(2\pi \cdot 100 \cdot 10^3)^2 \cdot 20.2 \times 10^{-9}} = 126\mu H \\
L_p = m \cdot L_r = 630\mu H 
\]
[STEP-6] Design the Transformer

The worst case for the transformer design is the minimum switching frequency condition, which occurs at the minimum input voltage and full-load condition. To obtain the minimum switching frequency, plot the gain curve using gain Equation 9 and read the minimum switching frequency. The minimum number of turns for the transformer primary-side is obtained as:

\[ N_p^{\text{min}} = \frac{n(V_o + V_F)}{2f_{s}^{\text{min}} \cdot M_v \cdot \Delta B \cdot A_v} \]  

(21)

where \( A_v \) is the cross-sectional area of the transformer core in \( \text{m}^2 \) and \( \Delta B \) is the maximum flux density swing in Tesla, as shown in Figure 20. If there is no reference data, use \( \Delta B = 0.3 \sim 0.4 \, \text{T} \).

Choose the proper number of turns for the secondary side that results in primary-side turns larger than \( N_p^{\text{min}} \) as:

\[ N_p = n \cdot N_s > N_p^{\text{min}} \]  

(22)

[Design Example] EER3542 core (\( A_v = 107 \, \text{mm}^2 \)) is selected for the transformer. From the gain curve of Figure 21, the minimum switching frequency is obtained as 78kHz. The minimum primary-side turns of the transformer is given as:

\[ N_p^{\text{min}} = \frac{n(V_o + V_F)}{2f_{s}^{\text{min}} \cdot \Delta B \cdot 1.11 \cdot A_v} \]

\[ = \frac{9.0 \times 24.9}{2 \cdot 77 \cdot 10^3 \cdot 0.4 \cdot 1.11 \cdot 107 \times 10^{-6}} = 30.5 \, \text{turns} \]

Choose \( N_s \) so that the resultant \( N_p \) should be larger than \( N_p^{\text{min}} \):

\[ N_p = n \cdot N_s = 1 \times 9.0 = 9 < N_p^{\text{min}} \]
\[ N_p = n \cdot N_s = 2 \times 9.0 = 18 < N_p^{\text{min}} \]
\[ N_p = n \cdot N_s = 3 \times 9.0 = 27 < N_p^{\text{min}} \]
\[ N_p = n \cdot N_s = 4 \times 9.0 = 36 > N_p^{\text{min}} \]

[STEP-7] Transformer Construction

Parameters \( L_p \) and \( L_r \) of the transformer were determined in STEP-5. \( L_p \) and \( L_r \) can be measured in the primary side with the secondary-side winding open circuited and short circuited, respectively. Since LLC converter design requires a relatively large \( L_r \), a sectional bobbin is typically used, as shown in Figure 22, to obtain the desired \( L_r \) value. For a sectional bobbin, the number of turns and winding configuration are the major factors determining the value of \( L_r \), while the gap length of the core does not affect \( L_r \) much. \( L_p \) can be easily controlled by adjusting the gap length. Table 2 shows measured \( L_p \) and \( L_r \) values with different gap lengths. A gap length of 0.10mm obtains values for \( L_p \) and \( L_r \) closest to the designed parameters.

Even though the integrated transformer approach in LLC resonant converter design can implement the magnetic components in a single core and save one magnetic component, the value of $L_r$ is not easy to control in real transformer design. Resonant network design sometimes requires iteration with a resultant $L_r$ value after the transformer is built. The resonant capacitor value is also changed since it should be selected among off-the-shelf capacitors. The final resonant network design is summarized in Table 3 and the new gain curves are shown in Figure 23.

Figure 23. Gain Curve of the Final Resonant Network Design

### [STEP-8] Select the Resonant Capacitor

When choosing the resonant capacitor, the current rating should be considered because a considerable amount of current flows through the capacitor. The RMS current through the resonant capacitor is given as:

$$I_{C_r}^{RMS} = \frac{1}{E_o} \sqrt{\frac{\pi I_{o, max}^2}{2} + \frac{n(V_o + V_f)}{4 \sqrt{2} f_o M_r (L_p - L_r)}}$$

The nominal voltage of the resonant capacitor in normal operation is given as:

$$V_{C_n}^{nom} = \frac{V_{in}^{max}}{2} + \frac{\sqrt{2} \cdot I_{C_r}^{RMS}}{2 \cdot \pi \cdot f_o \cdot C_r}$$

However, the resonant capacitor voltage increases much higher than this at overload condition or load transient. Actual capacitor selection should be based on the Over-Current Protection (OCP) trip point. With the OCP level, $I_{OCP}$, the maximum resonant capacitor voltage is obtained as:

$$V_{C_n}^{nom} = \frac{V_{in}^{max}}{2} + \frac{I_{OCP}}{2 \cdot \pi \cdot f_o \cdot C_r}$$

The peak current in the primary side in normal operation is:

$$I_{C_r}^{peak} = \sqrt{2} \cdot I_{C_r}^{rms} = 1.86A$$

The OCP level is set to 3.0A with 50% margin on $I_{C_r}^{peak}$.

[Design Example]

$$I_{C_r}^{RMS} = \frac{1}{E_o} \sqrt{\frac{\pi I_{o, max}^2}{2} + \frac{n(V_o + V_f)}{4 \sqrt{2} f_o M_r (L_p - L_r)}}$$

$$= \frac{1}{0.92} \sqrt{\frac{\pi \cdot 8 \cdot 9.0}{2 \cdot \sqrt{2} \cdot 9.0} + \frac{9.0(24 + 0.9)}{4 \sqrt{2} \cdot 99 \cdot 10^3 \cdot 11.1 \cdot 512 \cdot 10^6}}$$

$$= 1.32A$$

A 630V rated low-ESR film capacitor is selected for the resonant capacitor.

### [STEP-9] Rectifier Network Design

When the center tap winding is used in the transformer secondary side, the diode voltage stress is twice of the output voltage expressed as:

$$V_D = 2(V_o + V_f)$$

The RMS value of the current flowing through each rectifier diode is given as:

$$I_{D}^{RMS} = \frac{\pi}{4} I_o$$
Meanwhile, the ripple current flowing through output capacitor is given as:

\[
I_{Co\text{ RMS}} = \sqrt{\left(\frac{\pi I_o}{2\sqrt{2}}\right)^2 - I_o^2} = \sqrt{\frac{\pi^2 - 8}{8}} I_o
\]  

(28)

The voltage ripple of the output capacitor is:

\[
\Delta V_o = \frac{\pi}{2} I_o \cdot R_C
\]  

(29)

where \( R_C \) is the effective series resistance (ESR) of the output capacitor and the power dissipation is the output capacitor is:

\[
P_{\text{Loss,Co}} = (I_{Co\text{ RMS}})^2 \cdot R_C
\]  

(30)

**Design Example** The voltage stress and current stress of the rectifier diode are:

\[
\begin{align*}
V_D &= 2(V_o + V_r) = 2(24 + 0.9) = 49.8 \\
I_D\text{ RMS} &= \frac{\pi}{4} I_o = 6.28 A
\end{align*}
\]

The 100V/20A Schottky diode is selected for the rectifier considering the voltage overshoot caused by the stray inductance.

The RMS current of the output capacitor is:

\[
I_{Co\text{ RMS}} = \sqrt{\left(\frac{\pi I_o}{2\sqrt{2}}\right)^2 - I_o^2} = \sqrt{\frac{\pi^2 - 8}{8}} I_o = 3.857 A
\]

(31)

When two electrolytic capacitors with ESR of 80mΩ are used in parallel, the output voltage ripple is given as:

\[
\Delta V_o = \frac{\pi}{2} I_o \cdot R_C = \frac{\pi}{2} \cdot 8 \cdot \left( \frac{0.08}{2} \right) = 0.50 V
\]

(32)

The loss in electrolytic capacitors is:

\[
P_{\text{Loss,Co}} = (I_{Co\text{ RMS}})^2 \cdot R_C = 3.857^2 \cdot 0.04 = 0.60 W
\]

**[STEP-10] Control Circuit Configuration**

Figure 24 shows the typical circuit configuration for RT pin of FSFR-series, where the opto-coupler transistor is connected to the RT pin to control the switching frequency. The minimum switching frequency occurs when the opto-coupler transistor is fully turned off, which is given as:

\[
f_{\text{min}} = \frac{5.2 k\Omega}{R_{\text{min}}} \times 100 \text{ (kHz)}
\]  

(33)

Assuming the saturation voltage of opto-coupler transistor is 0.2V, the maximum switching frequency is determined as:

\[
f_{\text{max}} = \frac{5.2 k\Omega}{R_{\text{min}}} + \frac{4.68 k\Omega}{R_{\text{max}}} \times 100 \text{ (kHz)}
\]

(34)

**Soft-start**: To prevent excessive inrush current and overshoot of output voltage during start-up, increase the voltage gain of the resonant converter progressively. Since the voltage gain of the resonant converter is inversely proportional to the switching frequency, the soft-start is implemented by sweeping down the switching frequency from an initial high frequency \( f^{\text{ISS}} \) until the output voltage is established, as illustrated in Figure 25. The soft-start circuit is made by connecting RC series network on the RT pin as shown in Figure 24. FSFR-series also has an internal soft-start for 3ms to reduce the current overshoot during the initial cycles, which adds 40kHz to the initial frequency of the external soft-start circuit, as shown in Figure 25. The actual initial frequency of the soft-start is given as:

\[
f^{\text{ISS}} = \left( \frac{5.2 k\Omega}{R_{\text{min}}} + \frac{5.2 k\Omega}{R_{\text{SS}}} \right) \times 100 + 40 \text{ (kHz)}
\]

It is typical to set the initial frequency of soft-start \( f^{\text{ISS}} \) as 2–3 times of the resonant frequency \( f_o \).

The soft-start time is determined by the RC time constant:

\[
T_{\text{SS}} = 3 ~ 4 \text{ times of } R_{\text{SS}} \cdot C_{\text{SS}}
\]

Figure 25. Frequency Sweep of the Soft-start
(Design Example) The minimum frequency is 72kHz in STEP-6. \( R_{\text{min}} \) is determined as:

\[
R_{\text{min}} = \frac{100\,\text{kHz}}{f_{\text{min}}} \times 5.2\,\text{k}\Omega = 7.2\,\text{k}\Omega
\]

Considering the output voltage overshoot during transient (10%) and the controllability of the feedback loop, the maximum frequency is set as 140kHz. \( R_{\text{max}} \) is determined as:

\[
R_{\text{max}} = \frac{4.68\,\text{k}\Omega}{\frac{f_{\text{max}} \times 1.4}{100\,\text{kHz}} - \frac{5.2\,\text{k}\Omega}{100\,\text{kHz}}} = 7.1\,\text{k}\Omega
\]

Setting the initial frequency of soft-start as 250kHz (2.5 times of the resonant frequency), the soft-start resistor \( R_{\text{SS}} \) is given as:

\[
R_{\text{SS}} = \frac{5.2\,\text{k}\Omega}{\frac{f_{\text{SS}} - 40\,\text{kHz}}{100\,\text{kHz}} - \frac{5.2\,\text{k}\Omega}{100\,\text{kHz}}} = \frac{5.2\,\text{k}\Omega}{\frac{250\,\text{kHz} - 40\,\text{kHz}}{100\,\text{kHz}} - \frac{5.2\,\text{k}\Omega}{7.2\,\text{k}\Omega}} = 3.8\,\text{k}\Omega
\]

[STEP-11] Current Sensing and Protection

FSFR-series senses low-side MOSFET drain current as a negative voltage, as shown in Figure 26 and Figure 27. Half-wave sensing allows low-power dissipation in the sensing resistor, while full-wave sensing has less switching noise in the sensing signal. Typically, RC low-pass filter is used to filter out the switching noise in the sensing signal. The RC time constant of the low-pass filter should be 1/100–1/20 of the switching period.
Design Summary

Figure 28 shows the final schematic of the LLC resonant half-bridge converter design example. EER3542 core with sectional bobbin is used for the transformer. The efficiency at full load condition is around 94%.

6. Experimental Verification

To show the validity of the design procedure presented in this application note, the converter of the design example has been built and tested. All the circuit components are used as designed in the design example.

Figure 30 and Figure 31 show the operation waveforms at full-load and no-load conditions for nominal input voltage. As observed, the MOSFET drain-to-source voltage \( V_{DS} \) drops to zero by resonance before the MOSFET is turned on and zero voltage switching is achieved.

Figure 32 shows the waveforms of the resonant capacitor voltage and primary-side current at full-load condition. The peak values of the resonant capacitor voltage and primary-side current are 325V and 1.93A, respectively, which are well matched with the calculated values in STEP-8 of design procedure section. Figure 33 shows the waveforms of the resonant capacitor voltage and primary-side current at output-short condition. For output-short condition, over current protection (OCP) is triggered when the primary-side current exceeds 3A. The maximum voltage of the resonant capacitor is a little bit higher than the calculated value of 419V because the OCP trips at a level little bit higher than 3A, due to the shutdown delay time of 1.5\( \mu \)s (refer to the FSFR2100 datasheet).

Figure 34 shows the rectifier diode voltage and current waveforms at full-load and no-load conditions. Due to the voltage overshoot caused by stray inductance, the voltage stress is a little bit higher than the value calculated in STEP-9. Figure 35 shows the output voltage ripple at full-load and no-load conditions. The output voltage ripple is well matched with the designed value in STEP-9.

Figure 36 shows the measured efficiency for different load conditions. Efficiency at full-load condition is about 94%.
